IMY 320: UX Project Overview

Overview

The group project assignment is divided into 5 submissions that, over time, build a cohesive prototype of an online teaching service (think Udemy or Zenva). Your group is welcome to decide which "subject" your team plans to support.

The initial 3 submissions will be formatted as individual components that will make up your final website. Submission 4 is a compulsory UX evaluation. The final assignment will require you to complete the website, including all previously completed and new components.

For each submission, the group will receive a list of functions to complete and a problem statement (a quote from the owner) to be resolved based on a specific UX design principle covered in class.

The group is required to conduct **three** (per deliverable) short user experience research sessions on an existing website (UEQ shortened questionnaire), note any criteria that scored relatively low/high, and use this to formulate a set of design guidelines. This will also help you establish common feature trends or existing practices used within the industry.

Breakdown of submissions

Group Design A: Login page – 9 August

Group Design B: Products page – 23 August

Group Design C: Customer Experience – 27 September

Group Design D: UX Evaluation – 2 October

Group Design E: Final website – 25 October

The website's general operations should allow users to log in, browse courses, add courses to a cart, check out, and track their course progression.
Note: You do not need to create a teaching system for the content itself! You are creating a shell of what the website's general operations and experience should look like. You are welcome to add "placeholders" to replace certain functionalities (e.g., the learning system, the course content, etc.).

In addition to these general operations, your group needs to determine what other features might be needed and implement them accordingly. Remember, this is all about user experience.

Submission Format

This module does not require you to develop a fully working backend (It's highly recommended you do). However, functions such as purchasing history or cart interaction should still operate (JSON files are easy ways of manipulating these interactions), and each upload needs to be a stand-alone web application. This can be as simple as a set of HTML files or something built using any web-based framework.

Markers need to see and be able to interact with all elements of the website. Each button/link/operation needs to "operate" according to your final vision. This includes things like loading/progress bars, feedback on elements, error handling, real images, etc. You can think of it as developing the full, working front end of your website.

As explained in the study guide, completeness is a major criterion in the evaluation of all assignments. This means each component should be complete in both functionality and presentation.

- Functionality – would include features and capabilities that allow users to interact with and perform tasks on the site, such as navigating pages, submitting forms, and accessing dynamic content. (Even if they don't communicate with a backend, they need to appear that they do)
- Presentation – would refer to the visual and structural aspects of the site, including layout, design, and user interface elements, which ensure that all necessary information is displayed and accessible to users. (Including all animations and notifications)

The module itself doesn't prevent you from using any sort of tools or libraries in the development of your website. If you are using any existing library/framework, please indicate this clearly in your design (footer, fine print, etc.). Failure to do so will result in the project being flagged for plagiarism.

Other considerations

Although not a requirement, it is suggested that groups use version control software (GIT) and management software (Trello, Asana, etc.).
